Empowering Individuals with Limited Joint Mobility: An Embedded Interdisciplinary Program between Occupational Therapy & Industrial Design

Kyndra Adams, Andrew Berger, Tod Corlett, Eric Schneider, and Kimberly S. Mollo

Thomas Jefferson University, Occupational Therapy and Industrial Design Departments Philadelphia, PA 19107, USA

ABSTRACT

This paper highlights the third consecutive year of an ongoing, embedded interdisciplinary collaborative program between Occupational Therapy Doctoral (OTD) and Master of Industrial Design (design) students and faculty co-creating assistive devices that improve participation in tasks and activities for individuals living with Fibrodysplasia Ossificans Progressiva (FOP). FOP is a rare and progressive genetic disease, causing an individual's muscles, tendons, and ligaments to turn to bone, resulting in fixation and immobility. During the 9-month collaborative experience, OTD and design students co-conducted 2 sets of interviews with FOP clients identifying activities of daily living that were problematic secondary to individual disease course. OTD students administered the Canadian Occupational Performance Measure (COPM) to identify which daily routines and activities were impacted. Design students employed standardized questions to clarify how their activities were performed. Findings informed initial assistive device prototypes, which were then sent to FOP clients for user testing. After testing was completed, design students continued to prototype and conducted a second feedback interview. This program also included several interprofessional educational experiences designed by the OTD students for their design peers under occupational therapy (OT) and design faculty supervision. Content was created to reinforce FOP clients' needs and was delivered through shared learning modules, activities, and peer-to-peer discussion. Weekly collaboration occurring in design coursework between disciplines and use of OT-related tools such as the COPM, helped the design students leverage their skills by contextualizing what they observed when interacting with FOP clients, ultimately creating better products that met the needs of individuals with FOP. Findings presented include current data up to February 2022 from OTD and design interviews and FOP user feedback; data collection and prototyping will continue through May 2022. Outcomes demonstrated and reinforced the need for consistent, higher-level embedded interdisciplinary collaborative approaches that uniquely meet the needs of clients experiencing complex medical issues and help to expand the usability of assistive devices for other populations with complex issues.

Keywords: Interdisciplinary collaboration, Assistive devices, Design education

INTRODUCTION

One out of every four individuals in the United States currently lives with a disability that affects engagement in everyday valued activities (Centers for Disease Control and Prevention, 2018). By promoting independence, assistive devices can be life-changing for individuals with disabilities. Manufactured assistive devices available on the market include dressing sticks, reachers, and built-up handled utensils that improve grip and provide an ability to bring items closer to the body, allowing for greater independence in daily activities such as dressing, grooming, and eating.

With approximately 900 individuals diagnosed worldwide, FOP is a rare genetic disease in which an individual's muscles, tendons, and ligaments turn to bone through a process of heterotopic ossification (IFOPA 2021; Kaplan et al. 2021). Between childhood and early teen years, an individual begins to experience flare-ups in a progressive pattern starting in the neck and back, moving to the arms, hips, legs, and jaw, resulting in fixation. By middle to late adulthood, individuals with FOP become locked in awkward positions in which joint fusion occurred, limiting independence, and making daily activities difficult to execute. While no device on the market will meet the needs of every unique individual, populations with more complex physical needs (such as FOP) need to add custom modifications with materials found around the home or hardware store to improve usability. Although the creativity of homemade solutions allows for engagement in valued activities, individuals with FOP deserve to have access to assistive devices that are functional and durable, as well as aesthetically appealing to meet their needs.

Collaboration between designers and occupational therapists (OTs) has demonstrated benefits for end-user experience by contextualizing client conditions, user-feedback, environmental influences, and performance in everyday activities (Wagenfeld et al. 2017; Young et al. 2019). OTs are licensed healthcare professionals who help individuals regardless of age or functional ability regain independence and achieve desired goals through meaningful tasks or activities that they need or want to do. OT interventions are achieved through a client-centered approach, empowering the individual to guide treatment with the understanding that they are experts in their lives. Thus, the OT intervention process and the user-centered iterative design process are synonymous, as both require a deep understanding of the individual and the environmental influences that impact participation in everyday lives. For this reason, OTs are well suited to assist designers in leveraging their skills, providing contextualization and medical expertise for what is observed during task and activity engagement, resulting in the creation of better products that meet the end-user's needs.

Interprofessional education experiences are a longstanding mainstay between the occupational therapy and industrial departments at Thomas Jefferson University, an institution with strong connections to health care and design. For more than 20 years, these two departments have engaged in several ongoing interdisciplinary collaborative projects occurring at both the graduate and undergraduate levels, centered on creating assistive devices for assigned clients. In 2018, the university created an additional

continuous year-long, embedded interdisciplinary collaborative experience between Occupational Therapy Doctoral students (OTD) and Master of Industrial Design (design) students. Central to the current embedded interprofessional education experience is the collaborative assistive device design project for individuals with FOP. This paper explores the methodology and successes of the current FOP collaboration.

INTERDISCIPLINARY APPROACH TO PRODUCT DEVELOPMENT FOR LIMITED JOINT MOBILITY

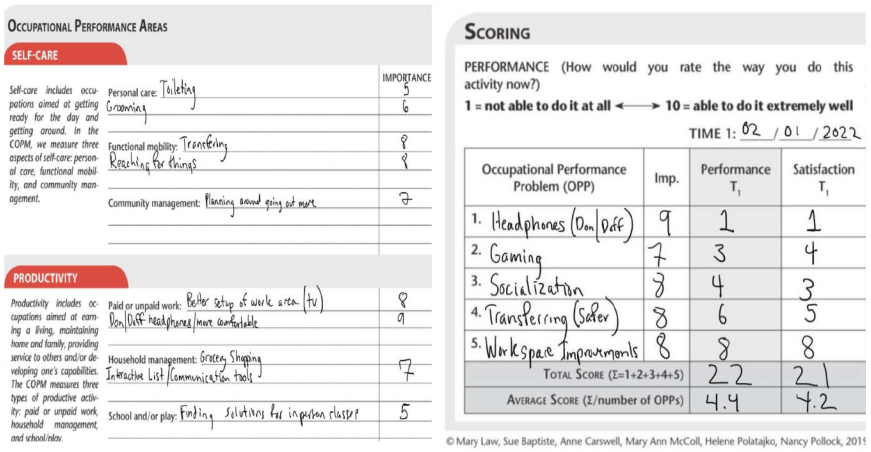
Studio Course

This year marks the fourth academic year of embedded OTD and design capstone experience and the third consecutive academic year of the FOP Collaboration. In August 2021, 2 OTD students were embedded with 5 Master of Industrial Design students in a summer bootcamp introductory design course. From September through December 2021, OTD students presented various modules and engaged in activities with the design students and faculty during studio class time to enhance understanding of OT scope of practice and to help prepare the design students for upcoming interactions with FOP clients. Collaborative studio time also allowed the OTD students to enhance their knowledge of industrial design, the iterative design process, and understand materials, processing, and manufacturing.

Methods

The current iteration of the FOP Project resumed in November 2021. OTD students first introduced FOP and explained the disease process to the design students which led to a discussion of the disease's impact on everyday activities. Students and faculty also virtually attended the International FOP Association (IFOPA) Family Gathering, an annual event in which members of the FOP community share information about assistive devices and learn about current developments in treating the condition. Here, students and faculty learned about homemade adaptations of "off the shelf" assistive devices, such as dressing sticks, reachers, and power wheelchair modifications. In December, OTD and design students collaborated to contextualize the information learned at the gathering with the intent to inform future device creation. Project areas of interest were then identified by the IFOPA family services coordinator as concerns affecting many community members. These included everyday activities such as grooming, oral hygiene, feeding, reaching, and using personal electronic devices.

In January 2022, 2 OTD and 5 design students co-conducted interviews with members of the FOP community via the Canadian Occupational Performance Measure (COPM) and interview questions specifically developed by OT and design faculty. IRB approval was granted by university prior to all data collection. OTD and design students co-interviewed 11 individuals from the FOP community referred by the IFOPA community coordinator (8 individuals with FOP and 3 caregivers of individuals with FOP).



OCCUPATIONAL PERFORMANCE AREAS

SELF-CARE

Self-care includes occupations aimed at getting ready for the day and getting around. In the COPM, we measure three aspects of self-care: personal care, functional mobility, and community management.

	IMPORTANCE
Personal care: Toileting	5
Grooming	6
Functional mobility: Transferring	8
Reaching for things	8
Community management: Planning around going out more	7

PRODUCTIVITY

Productivity includes occupations aimed at earning a living, maintaining home and family, providing service to others and/or developing one's capabilities. The COPM measures three types of productive activity: paid or unpaid work, household management, and school/play.

Paid or unpaid work: Better setup of work area (tv)	8
Don/Doff headphones/more comfortable	9
Household management: Grocery Shopping	7
Interactive List/Communication tools	
School and/or play: Finding solutions for in-person classes	5

SCORING

PERFORMANCE (How would you rate the way you do this activity now?)

1 = not able to do it at all ⟷ 10 = able to do it extremely well

TIME 1: 02 / 01 / 2022

Occupational Performance Problem (OPP)	Imp.	Performance T_1	Satisfaction T_1
1. Headphones (Don/Doff)	9	1	1
2. Gaming	7	3	4
3. Socialization	8	4	3
4. Transferring (Safer)	8	6	5
5. Workspace Improvements	8	8	8
TOTAL SCORE (Σ=1+2+3+4+5)		22	21
AVERAGE SCORE (Σ/number of OPPs)		4.4	4.2

Figure 1: Example of COPM problem identification and rating form.

The COPM is a client-reported outcome measure traditionally used in occupational therapy practice to help inform intervention planning and reassessment following OT treatment in the areas of self-care, productivity, and leisure (Law et al. 1990) (Figure 1). For the FOP Project, design students observed the OTD student COPM interview process, which provided a point of entry to performance challenges in daily tasks and activities of the FOP clients. Standardized reassessment with a tool such as the COPM can afford the opportunity to objectively evaluate the effectiveness of design prototypes, a methodology that is not traditionally used in the iterative process of product development (Schneider et al. 2019).

Following the administration of the COPM, the design students conducted a two-part interview with members of the FOP community. Part 1 focused on gaining information regarding how FOP clients currently engage in daily activities, including supports, barriers, and current device use. With information gleaned from both interviews, prototypes will be created and sent out for client testing (estimated March 2022). Design students will conduct a second interview (Part 2) to obtain user feedback as to how individuals with FOP use the device prototypes in their daily lives, and OTD students will complete a follow up COPM to determine change in performance and satisfaction in previously identified tasks and activities.

Iterations in Progress

As of the end of February 2022, all students have completed the initial COPM and Part 1 of the design interviews with members of the FOP community and are preparing to send out the first round of device prototypes. Through early May 2022, students will continue to iterate assistive device designs and conduct Part 2 of the design and COPM interviews. Both sets of interviews are being analyzed via NVivo software by the OTD students to elicit themes. The remainder of this paper explores the current stage of the assistive device designs and demonstrates how collaboration with OTD students affected the iterative design process.

Figure 2: Mockup of oral hygiene tool with extended handle.

Faculty report ongoing interactions between OTD and design students are leading to creative and holistic designs for the designers, and design students are helping OTD students encounter the innovative range of possible solutions when designing assistive devices for clients via an understanding of materials and technological possibilities. Through embedded learning in studio, faculty note that students have improved interview skills regarding follow-up questions, language for disability etiquette and empathy, preparing them to effectively interpret information obtained from interviews and increase comfort with clients. Input from OTD students also assisted in incorporating aspects of equitable use from universal design. Disability simulation-style exercises, active listening, and minimizing personal assumptions are enriching the design process by helping students better understand the impact of locked positioning for FOP clients on engagement in daily activities.

Project Descriptions

Oral Hygiene Device: Significant themes that emerged in the FOP interviews related to oral hygiene routines included 1) mobility restrictions in the arms, back, and neck that limit reach to the back of the mouth and 2) closed fixation of the jaw resulting in the inability to open the mouth to reach the backs of teeth. Current products are too large to adequately reach in between a fused jaw preventing clients from effectively cleaning their teeth, leading to dangerous levels of plaque buildup and related health complications. This device will fit into the jaw using a flexible head, can be contoured to the back of teeth via tongue, and will have an extended handle allowing for easy manipulation in the mouth (See Figure 2).

Personal Grooming Device: Fusion in the neck, back, shoulders, and elbows prevents reaching the top and the back of the head for individuals with FOP. The COPM indicated a desire for more independence in grooming, specifically hair brushing, while the design interviews detailed how current products are unsuitable due to limited grip and reach. The prototype handle allows for variability in arm position while affording greater control over the

Figure 3b: Prototype with updated compact handle configuration.

brush for more deliberate movements. An extendable shaft enables the brush to reach all areas of the head regardless of stature (See Figures 3a and 3b).

Power Straw: Fusing of the jaw and arms creates multifaceted difficulties with feeding, including getting food to the mouth effectively and types of food that can be consumed. The new device provides control over the rate and flow of food with a mechanical pump and extended straw, allowing for energy conservation when eating liquid or semi-liquid foods while being portable and discreet. Initially described as a "mechanical feeder," current students reflected on the potentially stigmatizing language when presenting the project and worked to move to a more inclusive language of "power straw." OTD students assisted in contextualizing and understanding information obtained from a speech and language pathologist to ensure the power straw is both a safe and effective method of food delivery (See Figures 4a and 4b).

Electromechanical Reacher: Interview findings indicated difficulty in picking up fallen objects, leading to dependency on caregivers. Current mass-produced reachers and grabbers increase reach to retrieve objects but require extended grip strength to hold the handle and gross motor control to orient

Figure 4a: Pressurized storage case holding liquid-food pouch and space for electronic controls and motor.

the device, which is difficult for FOP clients with severe mobility restrictions. An electromechanical reacher aims to reduce the effort needed to hold an object once it is picked up. A servo-claw at the end of the reacher will be controlled via a slider, improving the ability to grab items of various sizes. The range of fused positions in the FOP community requires reachers to be usable in varying positions, leading to introducing a joint at the handle allowing the shaft to move 180 degrees. FOP clients also emphasized the need for portability, which led to the designs incorporating a telescoping feature or foldable joint of the shaft. Design students remarked that a better

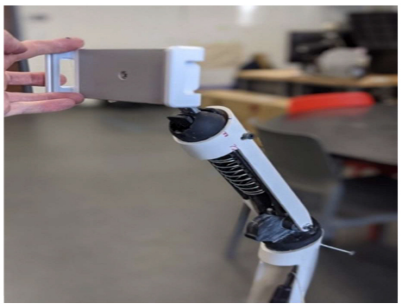

Figure 6b: Arm mounted on wheelchair with electronics holder attachment in alternate position.

understanding of user-centered and universal design concepts allowed them to effectively design the reacher to be useable by all members of the FOP community, regardless of fused positioning (See Figures 5a and 5b).

Wheelchair Electronics Mount: The wheelchair electronics mount was identified to improve the quality of interacting with electronics such as a mobile phone or tablet. Interview findings suggested that access to technology offers independence and connectedness, but restrictions in reach and upper body positioning limit usability. Available electronics holders on the market are bulky and hard to adjust and often require specific environmental positioning and assistance from a caregiver. An adjustable electronics mount allows for easier engagement and positioning when used or stored. Furthermore, the

wheelchair electronic mount enables individuals to use devices both in and outside of the home. Time spent collaborating allowed the design student to better understand how FOP clients desired to use their technology in their everyday lives, while the OTD students learned about how material choices impact the durability and adjustability of the device. (See Figures 6a and 6b)

CONCLUSION

The prototypes presented in this paper demonstrate improved product designs resulting from collaboration between disciplines that emphasized the unique needs of individuals with FOP, the end-users of these specific products. The IRB-approved, co-conducted student standardized interviews provided structure and focus to understand the lived experience and context of individuals living with FOP, and to frame the current issues in engagement with previously identified activities before jumping to a solution-oriented approach. Continual opportunities occurring during embedded coursework experiences strengthened the interdisciplinary collaboration between the students and led to rich discussions on the interview findings and contextualized information that led to different design approaches. Design students stated that knowledge shared in the classroom brought greater empathy and fostered a deeper connection to the user. Design students were able to better understand the impact and value of their work and were motivated to develop highly useable products that positively impact the quality of life for the FOP community through improved activity and task engagement. OTD students, while familiar with homemade solutions for an individual client, learned and developed a deeper understanding of how the iterative design process creates effective and aesthetically pleasing devices that can be mass-produced and used by larger populations. Current designs presented reflect work through February 2022; iterative processes and in-depth interview data analysis will continue until May 2022. User feedback will continue to support overarching goals to provide working prototypes to the FOP community and, eventually, to build a case for manufacturing the products. To date, initial findings support and reinforce the need for continual, consistent, higher-level embedded interdisciplinary collaborative approaches, ones that meet the needs of clients experiencing complex medical issues which can further expand the usability of assistive devices for other populations beyond FOP.
