ABSTRACT

Collaboration between humans and machines has demonstrated considerable potential. In the future, we can assume that humans and machines will collaborate in partnerships and sharing decision outcomes. This prompts us to examine the extent to which machine inputs are introduced and to clarify the accountability for both positive and negative outcomes. We conducted a questionnaire survey through social networks, collecting 123 valid responses. Respondents were tasked with imagining a collaborative scenario with an intelligent machine for a risky decision-making task. We compared decision weights and accountability assignments for decision outcomes (profit and/or loss) under different risky decision-making descriptions. We also analyzed accountability assignments under a range of human-machine partnerships with given decision weights. Our results revealed the preference of humans to take the lead in human-machine partnerships and they were willing to assume more accountability. We also observed significant differences between decision weight and the assignment of accountability for decision outcomes. Interestingly, a gender-based analysis indicated that women tended to favor higher decision weight in scenarios involving loss-sharing descriptions and were more likely to assume more accountability for negative outcomes. Furthermore, under given human-machine decision weights, both men and women participants took more accountability for profits than for losses. In particular, women compared to their male counterparts, tended to attribute significantly more accountability to themselves for losses. This study would facilitate work designs for human-machine teams and contribute to fostering better human-machine relationships.

Keywords: Human-machine collaboration, Decision weight, Accountability assignment, Human-machine team (HMT)

INTRODUCTION

The potential of human-machine collaboration has been prominently showcased in risky decision-making (Patel et al., 2019; Xiong et al., 2022). Machines can have an advantage in gathering information and assessing

uncertainty and can communicate key information to human decision-makers to save people's cognitive resources. Thus, developing suitable human-machine work design is of paramount importance.

Considerable research explored introducing machine input to varying degrees to achieve better performance or higher acceptance in human-machine teams (HMTs). Haesevoets et al., (2021) demonstrated that managers exhibited a preference for partnerships in which they held a majority vote regarding managerial decision-making outcomes. Their research indicated that a minimum of 70% human decision weight was necessary to achieve a sufficiently high level of acceptance, and any further increase in involvement did not yield additional gains in acceptance. De Cremer and McGuire (2022) indicated that individuals tended to favor a 60-40% human-algorithm partnership and perceived collaboration with autonomous algorithms as unfair when the algorithm takes the lead in decision-making. Our previous research (Xiong et al., 2023) also provided evidence that a 50-50% partnership outperformed individual human or machine decision-making in sequential risky decision-making.

Researchers also noticed the necessity of clarifying the accountability for both positive and negative outcomes. On the one hand, accountability assignments will influence people's satisfaction and acceptance of algorithms (Shin and Park, 2019). On the other hand, it will also impact human-machine relationships and HMT effectiveness. Dietvorst et al., (2015) demonstrated that people would lose confidence in imperfect machines when they witness them making mistakes and even choose a suboptimal human decision-maker instead. Shin and Park (2019) provided evidence to support the hypothesis that users would experience greater satisfaction when algorithms are held for the outcomes. As such, accountability assignments are critical aspects to consider in human-machine collaboration.

In the future, a greater variety of human-machine partnerships will emerge and human-machine collaboration will also face increasingly complex tasks. The increased risks and uncertainties place higher requirements on the attribution of authority and accountability in risky decision-making.

This paper aims to investigate how much weight and accountability humans prefer to cede to machines in risky decision-making under human-machine collaboration contexts. We examined preferences across different gender populations as well as under different risky decision-making descriptions. We also compare the human-machine accountability assignment under given human-machine decision weights.

METHOD

Questionnaire Design

Respondents were asked to imagine that they would be working with an intelligent machine (understood as APPs or products and/or the AI technology behind them) on a risky decision-making task.

The survey mainly included three parts:

(1) basic information collection (gender, age, education level, job and major);

(2) questions about decision weights and accountability assignment for decision outcomes (profit and/or loss) under different risky decision descriptions (no profit and loss sharing information, profit-sharing information only, loss-sharing information only, information on profit-sharing and loss-sharing). An example is shown in Figure 1.

当人机协同风险决策选择在决策恰当时，能够为人机团队带来收益，而在决策不当时将为人机团队造成损失时。此种情况下，人和机器将分配部分或全部收益，也将承担部分或全部损失。

Human-machine collaboration in risk decision-making will result in profits when the decisions are appropriate and result in losses when the decisions are inappropriate. In this case, human and machine will share some or all of the profits and will also bearsome or all of the losses.

Participants

We conducted a questionnaire survey through social networks. 127 questionnaires were returned. After removing invalid responses (excessive response time, more than 1200 seconds), 123 valid responses were retained. The average length of time spent answering the questionnaire was 439.67 seconds (SD = 192.15). Table 1 presents detailed characteristics of participants.

PREFERENCES FOR HUMAN DECISION WEIGHT AND ACCOUNTABILITY FOR OUTCOMES

In this section, we use the following abbreviations to indicate different ways of describing risk decisions: NoPL= No information about profit and loss; Ponly= Profit-sharing information only; Lonly=Loss-sharing information only; PL=Information on profit-sharing and loss-sharing.

Preferences for Human-Machine Decision Weight

We performed the Scheirer-Ray-Hare test and found a significant effect in gender ($p < 0.01$), an insignificant effect in risky decision-making scenarios

($p > 0.05$) and an insignificant interaction effect on preference for human decision weight ($H = 4.32$, $p = 0.23$). The Kruskal-Wallis test showed that women tended to favor higher decision weight in scenarios involving loss-sharing descriptions ($p < 0.05$). Figure 3 showed preferences for human decision weights of male and female participants under different descriptions of risky decision-making scenarios. Detailed data are listed in Table 3.

Figure 3: Preference for human decision weight across descriptions of risky decision-making scenarios (the level of significance in ANOVA or Non-parametric analysis: * = $p < 0.05$).

Preferences for Human-Machine Accountability Assignment

We performed the Scheirer-Ray-Hare test and found significant effects in genders and descriptions of risky decision-making scenarios ($p < 0.05$) and an insignificant interaction effect on preference for accountability for decision outcome ($H = 0.94$, $p = 0.79$).

As for the effects of gender, the Kruskal-Wallis tests showed that women were more likely to assign more accountability to themselves. In addition, men tended to assume more accountability under risky decision-making scenarios involving profit-sharing information compared to Lonely and NoPL scenarios ($ps < 0.05$), while women exhibited significantly different preference for human accountability between NoPL and scenarios involving profits (Ponly and PL) ($ps < 0.05$). Figure 4 showed preferences for accountability for decision outcomes of male and female participants under different descriptions of risky decision-making scenarios. Detailed data are listed in Table 3.

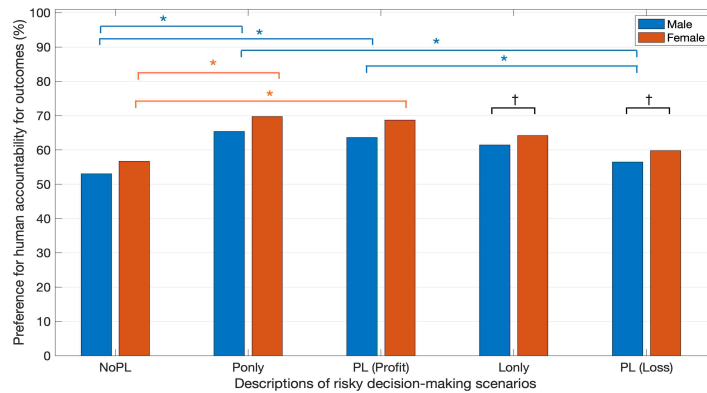

Figure 4: Preference for human accountability for decision outcomes (profits/losses) across descriptions of risky decision-making scenarios (the blue/red color represents the comparison results across different descriptions of risky decision-making scenarios in male/female participants, respectively; the level of significance in ANOVA or Non-parametric analysis: † = $p < 0.1$; * = $p < 0.05$).

Differences Between Decision Weight and Accountability Assignment

We used paired t-tests (or the Wilcoxon signed-rank test when the normality assumption was violated) to compare preferences for human decision weight and human accountability of male and female participants. All the differences were significant ($ps < 0.05$).

Table 2. Detailed data on preferences for human decision weight and accountability for outcomes.

Gender	Descriptions of risky decision-making scenario	Human decision weight(%) Mean (SD)	Human accountability of profits/losses(%) Mean (SD)	Sig
Male	NoPL	63.73 (16.38)	53.03 (19.59)	**
	Ponly	60.58 (18.91)	65.40 (16.36)	**
	Lonly	60.03 (16.64)	63.64 (18.93)	**
	PL	59.89 (16.88)	Profit: 59.09 (16.06) Loss: 53.66 (19.29)	**
Female	NoPL	63.84 (14.70)	56.73 (17.43)	**
	Ponly	63.72 (16.76)	69.74 (12.26)	**
	Lonly	66.04 (13.32)	68.71 (15.61)	**
	PL	66.28 (14.71)	Profit: 64.18 (14.60) Loss: 59.80 (20.96)	**

Note: the level of significance ANOVA or Non-parametric analysis. ** = $p < 0.01$.

PREFERENCES FOR ACCOUNTABILITY ASSIGNMENT UNDER GIVEN DECISION WEIGHTS

We draw preferences for accountability assignment for profits and losses under given human-machine decision weights of male and female participants in PL scenarios (shown in Figure 5 (a)(b)). The intersection point between the two curves and the reference line means the point at which the subject considers the decision weight to be equal to the assignment of accountability (50-50% partnership).

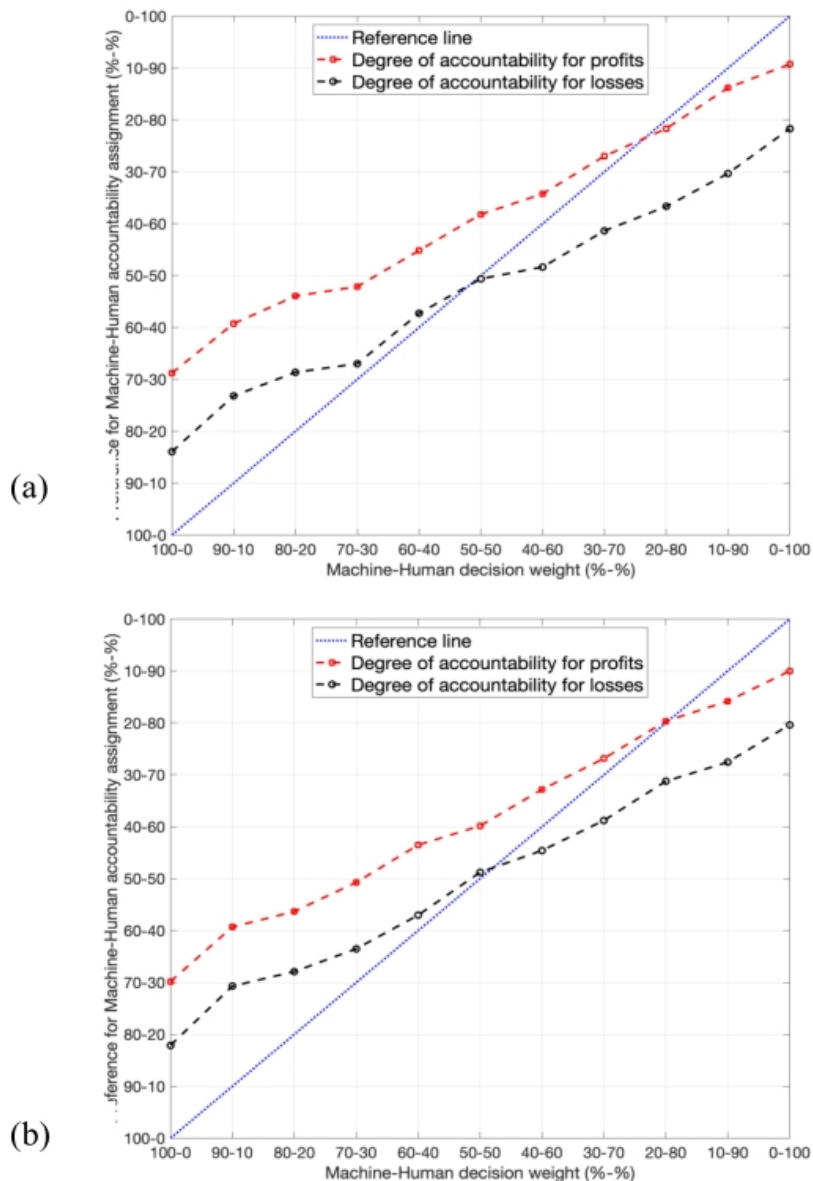

Figure 5: Preferences for accountability assignment for profits and losses under given human-machine decision weights: (a) male participants; (b) female participants.

The Wilcoxon signed-rank tests showed that both men and women participants attributed more accountability to themselves for profits than for losses ($ps < 0.05$). In particular, women tended to attribute more accountability to humans for losses, in comparison to their male counterparts ($p < 0.05$).

DISCUSSION AND CONCLUSION

Our paper revealed that humans do not want to exclude machines in collaborative risky decision-making but prefer to take the lead. This reflected the demand for control over the outcomes of the partnership (Zanatto et al., 2021). The significant difference between preferences for human decision weight and human accountability indicated HMT design cannot simply assume or set the two as consistent. This required further investigation and demonstration.

This study also focuses on the differential effects of gender and decision outcomes (positive and negative) on decision weight and accountability assignment. The gender difference in which female participants prefer higher human decision weight under loss-sharing scenarios represented more risk aversion, which was consistent with previous research (van Dolder & Vandembroucke, 2022). From the results of different descriptions of scenarios (involving loss-sharing information or not) and preferences for human accountability for decision outcomes (profits and/or losses), female participants were found to make more altruistic attributions compared to their male counterparts (Lei & Rau, 2021). That is, they assigned less accountability to their machine partners. In addition, both male and female participants exhibited self-serving bias (Miller & Ross, 1975) when assigning accountability profits and losses. They assigned more positive outcomes (profits) to themselves and more negative outcomes (losses) to external factors (i.e., machine partners).

This work also has some limitations. Firstly, the sample size could be expanded to yield more comprehensive and generalizable results. Secondly, limited by the method of questionnaire survey, the lack of actual human-machine interactions might affect participants' perceptions and ultimate results. Thirdly, more characteristics (such as age, and education level) should be considered to give a thorough analysis of human-machine decision weight and accountability assignment.

Our paper illustrates the preference of humans to take the lead in human-machine partnerships in risky decision-making and they are willing to assume more than half the accountability. Moreover, our analysis indicated female participants tended to be more risk averse and thus prefer more decision control over decision outcomes. Both female and male participants exhibited self-serving bias and assume more accountability for positive outcomes (profits). Female participants also make more altruistic attributions under scenarios involving loss-sharing descriptions compared to male counterparts. This study would facilitate work designs for HMTs and contribute to fostering better human-machine relationships.
